Searches for exclusive Higgs and Z boson decays into $J/\psi \gamma$, $\psi(2S) \gamma$, and $\Upsilon(nS) \gamma$ at $\sqrt{s} = 13$ TeV with the ATLAS detector

The ATLAS Collaboration

Searches for the exclusive decays of the Higgs and Z bosons into a J/ψ , $\psi(2S)$, or $\Upsilon(nS)$ ($n = 1, 2, 3$) meson and a photon are performed with a pp collision data sample corresponding to an integrated luminosity of 36.1 fb^{-1} collected at $\sqrt{s} = 13$ TeV with the ATLAS detector at the CERN Large Hadron Collider. No significant excess of events is observed above the expected backgrounds, and 95% confidence-level upper limits on the branching fractions of the Higgs boson decays to $J/\psi \gamma$, $\psi(2S) \gamma$, and $\Upsilon(nS) \gamma$ of 3.5×10^{-4} , 2.0×10^{-3} , and $(4.9, 5.9, 5.7) \times 10^{-4}$, respectively, are obtained assuming Standard Model production. The corresponding 95% confidence-level upper limits for the branching fractions of the Z boson decays are 2.3×10^{-6} , 4.5×10^{-6} and $(2.8, 1.7, 4.8) \times 10^{-6}$, respectively.

1 Introduction

Following the observation of a Higgs boson H with a mass of approximately 125 GeV by the ATLAS and CMS collaborations [1, 2], detailed measurements of its properties show no deviations from the SM. However, its role in fermion mass generation is still to be shown experimentally. In the Standard Model (SM), this mass generation is implemented through Yukawa interactions, and many theories beyond the SM predict substantial modifications of the relevant Higgs boson couplings to fermions. The ATLAS and CMS collaborations have reported measurements of the Higgs coupling to a third-generation fermion with a significance greater than five standard deviations in the $H \rightarrow \tau^+\tau^-$ channel [3–5]. In addition, progress has been made in the third-generation quark sector with indirect evidence of the coupling of the Higgs boson to the top quark [3]. This was recently complemented by direct observation of the associated production of the Higgs boson with a top-quark pair ($t\bar{t}H$) [6, 7]. Evidence of Higgs boson decays into $b\bar{b}$ has also been found with a significance in excess of three standard deviations by both ATLAS and CMS [8–10]. No experimental evidence of Higgs boson decays into the first- and second-generation fermions has yet been found, but direct searches were recently performed by the ATLAS Collaboration for $H \rightarrow c\bar{c}$ [11] and $H \rightarrow \mu^+\mu^-$ [12, 13] and by the CMS Collaboration for $H \rightarrow \mu^+\mu^-$ and $H \rightarrow e^+e^-$ decays [14].

The Standard Model Higgs boson decays $H \rightarrow J/\psi \gamma$ and $H \rightarrow \psi(2S) \gamma$ offer an opportunity to access the charm-quark Yukawa coupling [15, 16] in a manner complementary to studies of the inclusive decay $H \rightarrow c\bar{c}$. The branching fractions for $H \rightarrow J/\psi \gamma$ and $H \rightarrow \psi(2S) \gamma$ have been calculated within the SM to be $\mathcal{B}(H \rightarrow J/\psi \gamma) = (2.99^{+0.16}_{-0.15}) \times 10^{-6}$ [17]. Other recent results on these calculations are given in Refs. [18–20]. For $H \rightarrow \psi(2S) \gamma$ the branching fraction was calculated by the authors of Ref. [17] to be $\mathcal{B}(H \rightarrow \psi(2S) \gamma) = (1.03 \pm 0.06) \times 10^{-6}$ using an estimate for the value of the order- v^2 NRQCD long-distance matrix element.

The corresponding decays in the bottomonium sector, $H \rightarrow \Upsilon(1S, 2S, 3S) \gamma$, can provide, in combination with $H \rightarrow b\bar{b}$ decays, information about the real and imaginary parts of the b -quark coupling to the Higgs boson [19]. However, the expected SM branching fractions, $\mathcal{B}(H \rightarrow \Upsilon(nS) \gamma) = (5.22^{+2.02}_{-1.70}, 1.42^{+0.72}_{-0.57}, 0.91^{+0.48}_{-0.38}) \times 10^{-9}$ ($n = 1, 2, 3$) [17, 18], are smaller due to a cancellation between the “direct” and “indirect” amplitudes. The direct amplitude proceeds through the $H \rightarrow q\bar{q}$ coupling with a subsequent photon emission before the $q\bar{q}$ hadronisation to $\Upsilon(nS)$. The indirect amplitude proceeds via the $H\gamma\gamma$ coupling followed by the fragmentation $\gamma^* \rightarrow \Upsilon(nS)$.

Deviations of the c - and b -quark Yukawa couplings from the SM expectations can lead to significant increases in the branching fractions for exclusive decays. These deviations can arise in beyond-the-SM theories; for example, the quark masses might not originate entirely from the Higgs mechanism but could also be induced by other subdominant sources of electroweak symmetry breaking [21]. Other scenarios include the minimal flavour violation framework [22], the Froggatt–Nielsen mechanism [23], the Higgs-dependent Yukawa couplings model [24], the Randall–Sundrum family of models [25], and the possibility of the Higgs boson being a composite pseudo-Goldstone boson [26]. An overview of relevant models of physics beyond-the-SM is provided in Ref. [27].

Decays of the Higgs boson into a heavy, vector quarkonium state, $Q \equiv J/\psi$ or $\Upsilon(nS)$, and a photon were searched for by the ATLAS Collaboration with up to 19.2 fb^{-1} of data collected at $\sqrt{s} = 8 \text{ TeV}$ [28], resulting in 95% confidence level (CL) upper limits of 1.5×10^{-3} for $\mathcal{B}(H \rightarrow J/\psi \gamma)$ and $(1.3, 1.9, 1.3) \times 10^{-3}$ for $\mathcal{B}(H \rightarrow \Upsilon(nS) \gamma)$ ($n = 1, 2, 3$). The former decay mode was also searched for by the CMS

Collaboration [29], yielding a similar upper limit. In addition, the ATLAS Collaboration searched for the rare Higgs decays $H \rightarrow \phi \gamma$ and $H \rightarrow \rho \gamma$ [30, 31].

Owing to the large Z boson production cross section at the LHC, rare Z boson decays can be probed at much lower rates than for Higgs boson decays into the same final state. Branching fractions for $Z \rightarrow Q \gamma$ decays have been calculated to be between 10^{-8} and 10^{-7} for both the $Z \rightarrow J/\psi \gamma$ and $Z \rightarrow \Upsilon(nS) \gamma$ decays [32–34]. Measurements of the branching fractions for these decays would provide a sensitive test of the SM and the factorisation approach in quantum chromodynamics (QCD), since the power corrections in terms of the ratio of the QCD energy scale to the vector-boson mass are small [33]. ATLAS searched for Z boson decays into J/ψ or $\Upsilon(nS)$ ($n = 1, 2, 3$) and a photon with 20.3 fb^{-1} of data collected at $\sqrt{s} = 8 \text{ TeV}$ [28], resulting in 95% CL upper limits of 2.6×10^{-6} and $(3.4, 6.5, 5.4) \times 10^{-6}$, respectively. ATLAS also searched for the decay modes $Z \rightarrow \phi \gamma$ and $Z \rightarrow \rho \gamma$ [30, 31].

This Letter describes searches for Higgs and Z boson decays into the exclusive final states $J/\psi \gamma$, $\psi(2S) \gamma$, and $\Upsilon(nS) \gamma$ ($n = 1, 2, 3$) with $J/\psi \rightarrow \mu^+ \mu^-$, $\psi(2S) \rightarrow \mu^+ \mu^-$, and $\Upsilon(nS) \rightarrow \mu^+ \mu^-$ using ATLAS data collected in 2015 and 2016 at $\sqrt{s} = 13 \text{ TeV}$. Throughout the remainder of this Letter, where no distinction is relevant, the J/ψ and $\psi(2S)$ states are referred to collectively as the $\psi(nS)$ states.

2 ATLAS detector

ATLAS [35] is a multipurpose particle detector with a forward–backward symmetric cylindrical geometry and near 4π coverage in solid angle.¹ It consists of an inner tracking detector, electromagnetic and hadronic calorimeters, and a muon spectrometer.

The inner tracking detector (ID) covers the pseudorapidity range $|\eta| < 2.5$ and is surrounded by a thin superconducting solenoid providing a 2 T magnetic field. At small radii, a high-granularity silicon pixel detector surrounds the vertex region and typically provides four measurements per track. It is followed by a silicon microstrip tracker, which provides eight measurement points per track. The silicon detectors are complemented by a gas-filled straw-tube transition radiation tracker, which enables radially extended track reconstruction up to $|\eta| = 2.0$ with typically 35 measurements per track.

Electromagnetic (EM) calorimetry within the region $|\eta| < 3.2$ is provided by barrel and endcap high-granularity lead/liquid-argon (LAr) EM calorimeters with an additional thin LAr presampler covering $|\eta| < 1.8$ to correct for energy loss in upstream material; for $|\eta| < 2.5$ the EM calorimeter is divided into three layers in depth. A steel/scintillator-tile calorimeter provides hadronic calorimetry for $|\eta| < 1.7$. LAr technology with copper as absorber is used for the hadronic calorimeters in the endcap region $1.5 < |\eta| < 3.2$. The solid-angle coverage is completed with forward copper/LAr and tungsten/LAr calorimeter modules in $3.1 < |\eta| < 4.9$ optimised for EM and hadronic measurements, respectively.

The muon spectrometer surrounds the calorimeters and has separate trigger and high-precision tracking chambers measuring the deflection of muons in a magnetic field provided by three air-core superconducting toroidal magnets. The precision chamber system covers the region $|\eta| < 2.7$ with three layers of monitored drift tubes, complemented by cathode strip chambers in the forward region. The muon trigger system

¹ ATLAS uses a right-handed coordinate system with its origin at the nominal interaction point (IP) in the centre of the detector and the z -axis along the beam pipe. The x -axis points from the IP to the centre of the LHC ring, and the y -axis points upward. Cylindrical coordinates (r, ϕ) are used in the transverse plane, ϕ being the azimuthal angle around the z -axis. The pseudorapidity is defined in terms of the polar angle θ as $\eta = -\ln \tan(\theta/2)$.

covers the range $|\eta| < 2.4$ with resistive plate chambers in the barrel and thin gap chambers in the endcap regions.

A two-level trigger and data acquisition system is used to record events for offline analysis [36]. The level-1 trigger is implemented in hardware and uses a subset of detector information to reduce the event rate to at most 100 kHz. It is followed by a software-based high-level trigger which filters events using the full detector information and outputs events for permanent storage at an average rate of 1 kHz.

3 Data and simulated data

The search is performed with a sample of pp collision data recorded at a centre-of-mass energy $\sqrt{s} = 13$ TeV corresponding to an integrated luminosity of 36.1 fb^{-1} . The integrated luminosity of the data sample has an uncertainty of 2.1% derived using the method described in Ref. [37]. Events are retained for further analysis only if they were collected under stable LHC beam conditions and all relevant detector components were fully functional.

The data samples used in this analysis were collected by a combination of two triggers [36]. The first required an isolated photon with transverse momentum p_T^γ greater than 35 GeV and at least one muon with p_T^μ greater than 18 GeV. The second required an isolated photon with $p_T^\gamma > 25$ GeV and a muon with $p_T^\mu > 24$ GeV.

Higgs boson production was modelled using the POWHEG-Box v2 Monte Carlo (MC) event generator [38–42] with CT10 parton distribution functions [43] for the gluon–gluon fusion (ggH) and vector-boson fusion (VBF) processes. Both processes were calculated up to next-to-leading order (NLO) in α_s . POWHEG-Box was interfaced with PYTHIA 8.186 [44, 45] to model the parton shower, hadronisation, and underlying event with the AZNLO set of tuned parameters [46]. Additional contributions from the associated production of a Higgs boson and a W or Z boson (denoted WH and ZH , respectively) were modelled by the PYTHIA 8.186 event generator [44, 45] with NNPDF23LO parton distribution functions [47] and the A14 set of tuned parameters for hadronisation and the underlying event [48]. The production rates for the SM Higgs boson with $m_H = 125$ GeV, obtained from the compilation in Ref. [27], are assumed throughout this analysis. The ggH production is normalised such that it reproduces the total cross section predicted by a next-to-next-to-next-to-leading-order QCD calculation with NLO electroweak corrections applied [49–52]. The VBF production is normalised to an approximate next-to-next-to-leading-order (NNLO) QCD cross section with NLO electroweak corrections applied [53–55]. The production of WH and ZH is normalised to cross sections calculated at NNLO in QCD with NLO electroweak corrections [56, 57] including the NLO QCD corrections [58] for $gg \rightarrow ZH$. The production of a Higgs boson in association with $t\bar{t}$ ($t\bar{t}H$) or $b\bar{b}$ ($b\bar{b}H$) is accounted for by scaling the total cross section used to normalise the ggH signal sample, assuming the signal efficiency of these processes to be equal to that for ggH . The addition of $t\bar{t}H$ and $b\bar{b}H$ to the ggH signal changes the acceptance by less than 1%.

The POWHEG-Box v2 event generator was also used to model inclusive Z boson production. PYTHIA 8.186 [44, 45] with CTEQ6L1 parton distribution functions [59] and the AZNLO set of hadronisation and underlying-event parameters [46] was used to simulate parton showering and hadronisation. The prediction is normalised to the total cross section obtained from the measurement in Ref. [60], which has an uncertainty of 2.9%. This conservatively assumes the luminosity component of the uncertainty to be completely uncorrelated with that of this search. The Higgs and Z boson decays were simulated as a cascade of two-body decays, accounting for effects of the quarkonium helicity on the $\mu^+\mu^-$ kinematics.

The branching fractions for the decays $Q \rightarrow \mu^+ \mu^-$ are taken from Ref. [61]. The simulated events were passed through the detailed GEANT 4 simulation of the ATLAS detector [62, 63] and processed with the same software used to reconstruct the data.

4 Event selection for $\psi(nS)\gamma \rightarrow \mu^+ \mu^- \gamma$ and $\Upsilon(nS)\gamma \rightarrow \mu^+ \mu^- \gamma$

Muons are reconstructed from ID tracks combined with independent muon spectrometer tracks or track segments [64] and are required to have $p_T^\mu > 3$ GeV and pseudorapidity $|\eta^\mu| < 2.5$. Candidate $Q \rightarrow \mu^+ \mu^-$ decays are reconstructed from pairs of oppositely charged muons consistent with originating from a common vertex. The highest- p_T muon in a pair, called the leading muon in the following, is required to have $p_T^\mu > 18$ GeV. Dimuons with a mass $m_{\mu^+ \mu^-}$ within $2.0 < m_{\mu^+ \mu^-} < 4.2$ GeV are identified as $\psi(nS) \rightarrow \mu^+ \mu^-$ candidates. Dimuons with $8.0 < m_{\mu^+ \mu^-} < 12.0$ GeV are considered to be $\Upsilon(nS) \rightarrow \mu^+ \mu^-$ candidates.

Selected $Q \rightarrow \mu^+ \mu^-$ candidates are subjected to isolation and vertex-quality requirements. In this case, the primary pp vertex is defined as the reconstructed vertex with the highest $\sum_i p_{T_i}^2$ of all associated tracks used to form the vertex. The sum of the p_T of the tracks within $\Delta R = \sqrt{(\Delta\phi)^2 + (\Delta\eta)^2} = 10 \text{ GeV}/p_T^\mu$ (with a maximum ΔR of 0.3) of the leading muon is required to be less than 6% of the muon p_T [65]. To mitigate the effects of multiple pp interactions in the same or neighbouring bunch crossings, only ID tracks that originate from the primary vertex are considered. The transverse momentum of the ID track associated with the leading muon is subtracted from the sum, and the subleading muon is also subtracted if it falls within the isolation cone. To reject backgrounds from b -hadron decays, the signed projection of the Q candidate's flight distance between the primary pp vertex and the dimuon vertex onto the direction of its transverse momentum is required to be less than three times its uncertainty.

Photons are reconstructed from clusters of energy in the electromagnetic calorimeter. Clusters without matching ID tracks are classified as unconverted photon candidates while clusters matched to ID tracks consistent with the hypothesis of a photon conversion into $e^+ e^-$ are classified as converted photon candidates [66]. Reconstructed photon candidates are required to have transverse momentum $p_T^\gamma > 35$ GeV and pseudorapidity $|\eta^\gamma| < 2.37$, excluding the barrel/endcap calorimeter transition region $1.37 < |\eta^\gamma| < 1.52$, and to satisfy the “tight” photon identification criteria [66]. Isolation requirements are imposed to further suppress the contamination from jets. The sum of the transverse momenta of all tracks originating from the primary vertex, within $\Delta R = 0.2$ of the photon direction, excluding those associated with reconstructed photon conversions, is required to be less than 5% of p_T^γ . In addition to this track isolation criterion, a calorimeter isolation criterion is applied where the sum of the transverse momenta of calorimeter energy clusters within $\Delta R = 0.4$ of the photon direction, excluding the transverse energy of the reconstructed photon, is required to be less than $(2.45 \text{ GeV} + 0.022 p_T^\gamma)$. The effects of multiple pp interactions in the events are also accounted for in the calorimeter isolation measurements.

Combinations of a $Q \rightarrow \mu^+ \mu^-$ candidate and a photon satisfying $\Delta\phi(Q, \gamma) > \pi/2$ are retained for further analysis. When multiple combinations are possible, a situation that arises in only a few percent of the events, the combination of the highest- p_T photon and the Q candidate with an invariant mass closest to the respective quarkonium mass is retained. To improve the sensitivity of the $\Upsilon(nS)\gamma$ analysis in resolving the individual $\Upsilon(nS)$ states, the events are classified into two exclusive categories based upon the pseudorapidity of the muons. Events where both muons are within the region $|\eta^\mu| < 1.05$ constitute the

“barrel” (B) category. Events where at least one of the muons is outside the region $|\eta^\mu| < 1.05$ constitute the “endcap” (EC) category.

To maintain a single search region, while ensuring near-optimal sensitivity for both the Higgs and Z boson analyses, the transverse momentum of the Q candidate p_T^Q is required to be greater than a value that varies as a function of the invariant mass of the three-body system $m_{Q\gamma}$. For the $\psi(nS) \rightarrow \mu^+\mu^-$ ($\Upsilon(nS) \rightarrow \mu^+\mu^-$) selection, p_T^Q thresholds of 40 GeV (34 GeV) and 54.4 GeV (52.7 GeV) are imposed for the regions $m_{Q\gamma} \leq 91$ GeV and $m_{Q\gamma} \geq 140$ GeV, respectively. The thresholds are varied between their minimum and maximum values as a linear function of $m_{Q\gamma}$ in the region $91 \text{ GeV} < m_{Q\gamma} < 140 \text{ GeV}$.

5 Signal modelling

For the $\psi(nS) \gamma \rightarrow \mu^+\mu^- \gamma$ final state, the total signal efficiencies (kinematic acceptance, trigger, reconstruction, identification, and isolation efficiencies) are 19% and 11% for the Higgs and Z boson decays, respectively. The corresponding efficiencies for the $\Upsilon(nS) \gamma \rightarrow \mu^+\mu^- \gamma$ final states are 22–23% and 15–16%, respectively. The difference in efficiency between the Higgs and Z boson decays arises primarily from the softer p_T^γ and $p_T^{\mu\mu}$ distributions associated with $Z \rightarrow Q \gamma$ production, as seen by comparing Figures 1(a) and 1(b) for the $J/\psi \gamma$ case and Figures 1(c) and 1(d) for the $\Upsilon(nS) \gamma$ case.

Accounting for quarkonium helicity effects in the $Q \rightarrow \mu^+\mu^-$ decays leads to a 3–4% decrease of the expected Higgs boson efficiency and a corresponding 6–9% increase of the expected Z boson efficiency.

The $m_{\mu^+\mu^- \gamma}$ resolution is 1.6–1.8% for both the Higgs and Z boson decays. For each of the final states, a two-dimensional ($m_{\mu^+\mu^- \gamma}$ and $m_{\mu^+\mu^-}$) probability density function (pdf) is used to model the signal. The Higgs boson signals are modelled with two-dimensional multivariate Gaussian distributions, which retain the correlation between $m_{\mu^+\mu^- \gamma}$ and $m_{\mu^+\mu^-}$ of the final states. For the Z boson decays, the $m_{\mu^+\mu^- \gamma}$ distributions of the signal are modelled with Voigtian pdfs (a convolution of Breit–Wigner and Gaussian pdfs) corrected with mass-dependent efficiency factors, and the $m_{\mu^+\mu^-}$ distributions are modelled as Gaussian pdfs.

The $m_{\mu^+\mu^-}$ distribution for selected $\psi(nS) \gamma$ candidates, which pass the background generation region criteria described in Section 6, is shown in Figure 2(a) and exhibits clear peaks at the J/ψ and $\psi(2S)$ masses. In Figures 2(b) and 2(c), the corresponding distributions for the selected $\Upsilon(nS) \gamma$ candidates are shown, where the $\Upsilon(1S, 2S, 3S)$ peaks can be observed. The $\psi(nS)$ and $\Upsilon(nS)$ peaks are fitted with Gaussian pdfs and are used to cross-check the parameters obtained from the fit to simulated signal event samples, while the background is modelled with a Chebychev polynomial function. The experimental resolution in $m_{\mu^+\mu^-}$ is approximately 54 MeV for the $J/\psi \gamma$ candidates (43 MeV for events in the barrel category and 64 MeV for events in the endcap category).

6 Background modelling

The dominant source of background exhibits a non-resonant $m_{\mu^+\mu^- \gamma}$ distribution and is composed of two distinct contributions: genuine $Q \rightarrow \mu^+\mu^-$ decays and non-resonant dimuon production. The decay $Z \rightarrow \mu^+\mu^- \gamma$ with final-state radiation (Z FSR) constitutes a further, smaller background contribution exhibiting a characteristic resonant structure in the $m_{\mu^+\mu^- \gamma}$ distribution.

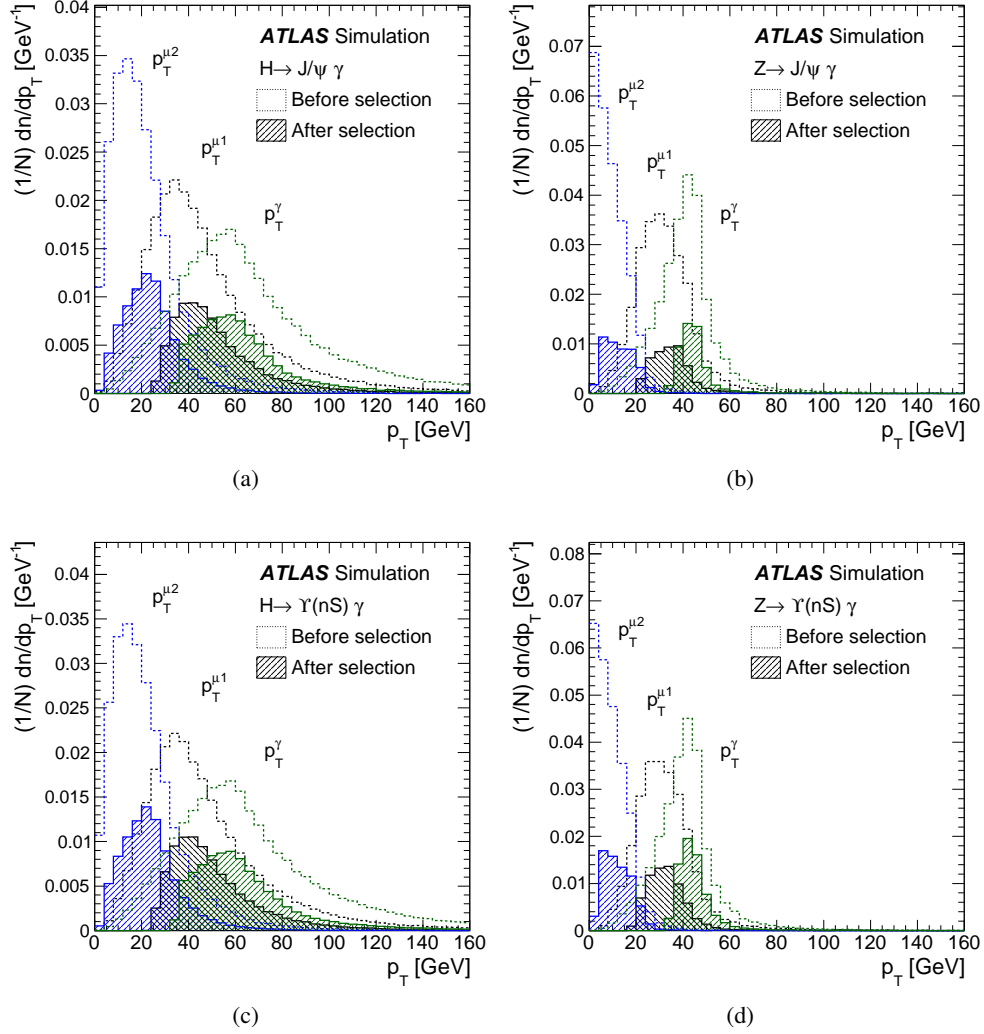

Figure 1: Generator-level transverse momentum (p_T) distributions of the photon and of the muons, ordered in p_T , for (a) $H \rightarrow J/\psi \gamma$, (b) $Z \rightarrow J/\psi \gamma$, (c) $H \rightarrow \Upsilon(nS) \gamma$ and (d) $Z \rightarrow \Upsilon(nS) \gamma$ simulated signal events, respectively. The leading muon candidate is denoted by $p_T^{\mu 1}$ and the subleading candidate by $p_T^{\mu 2}$. The hatched histograms denote the full event selection while the dashed histograms show the events at generator level that fall within the analysis geometric acceptance (both muons are required to have $|\eta^\mu| < 2.5$ while the photon is required to have $|\eta^\gamma| < 2.37$, excluding the region $1.37 < |\eta^\gamma| < 1.52$). The dashed histograms are normalised to unity, and the relative difference between the two sets of distributions corresponds to the effects of reconstruction, trigger, and event selection efficiencies.

The $m_{\mu^+\mu^-\gamma}$ continuum background is modelled with a non-parametric data-driven approach using templates to describe the kinematic distributions. The normalisation of the background is extracted directly from a fit to the data. The shape of the background model in the final discriminant variable is also profiled in the fit. A similar procedure was used in the earlier search for Higgs and Z boson decays into $J/\psi \gamma$ and $\Upsilon(nS) \gamma$ [28] and the searches for Higgs and Z boson decays into $\phi \gamma$ and $\rho \gamma$ [30, 31].

The background model uses a sample of 5500 $\psi(nS) \gamma$ and 2300 $\Upsilon(nS) \gamma$ candidate events. These events pass all of the kinematic selection requirements described previously, except that the photon and

(a)

(b)

(c)

Figure 2: Distribution of $\mu^+\mu^-$ invariant mass for (a) $\psi(nS)\gamma$ and $Y(nS)\gamma$ ((b) barrel and (c) endcap categories) candidates. The candidates satisfy the event selection but without the nominal isolation requirements and with a looser minimum p_T^Q requirement of 30 GeV. These events constitute the background “generation region” defined in Section 6.

Q candidates are not required to satisfy the nominal isolation requirements and a looser minimum p_T^Q requirement of 30 GeV is imposed. These events define the background-dominated “generation region” (GR). From these events, pdfs are constructed to describe the distributions of the relevant kinematic and isolation variables and their most important correlations. The data control samples are corrected for contamination from $Z \rightarrow \mu^+\mu^-\gamma$ decays.

The pdfs of these kinematic and isolation variables are sampled to generate an ensemble of pseudocandidates, each with complete Q and γ four-vectors and the associated Q and photon isolation values. The important correlations among the kinematic and isolation variables of the background events, in particular

between p_T^Q and p_T^γ , are retained in the generation of the pseudocandidates through the following sampling scheme:

- Initially, a value for p_T^Q is sampled from the corresponding pdf.
- The distribution of p_T^γ is parameterised in bins of p_T^Q , and a value is sampled from the corresponding bin given the previously sampled value of p_T^Q . The muon isolation variables are parameterised in bins of p_T^Q and p_T^γ and sampled according to the previously selected values.
- The distributions of the pseudorapidity difference between Q and γ , $\Delta\eta(Q, \gamma)$, the photon calorimeter isolation variable, and their correlations are parameterised in a binned two-dimensional distribution in the same bins of p_T^Q used to describe the p_T^γ and muon isolation variables.
- Given the selected values of relative photon calorimeter isolation and p_T^Q , a value for the relative photon track isolation is sampled.
- Given the selected values of $\Delta\eta(Q, \gamma)$ and p_T^Q , a value is sampled for the azimuthal angular separation between Q and γ , $\Delta\phi(Q, \gamma)$.
- Values for η^Q and ϕ^Q are sampled from a binned histogram of the corresponding distributions in the data control sample. These are combined with $\Delta\eta(Q, \gamma)$ and $\Delta\phi(Q, \gamma)$ to give the values of η^γ and ϕ^γ .
- A value for m_Q is sampled from within the required region of $m_{\mu^+\mu^-}$. Separate pdfs are used to describe the $m_{\mu^+\mu^-}$ distributions of resonant $\psi(nS)$ and $\Upsilon(nS)$ production and non-resonant dimuons, which is referred to as “combinatoric” in the following.

The use of this procedure ensures a good description of the background and avoids any reliance on the accuracy or limited sample size of simulated background events.

The nominal selection requirements are imposed and the surviving pseudocandidates are used to construct templates for the $m_{Q\gamma}$ distributions which are then smoothed using a Gaussian kernel density estimation [67]. Potential contamination of the GR sample from signal events is expected to be negligible, and it was verified, through signal injection tests, that such a potential signal contamination would not affect the shape of the background model.

The normalisation of the exclusive background from Z FSR is determined directly from the fit to the data. The shape of this background in the $m_{\mu^+\mu^-}\gamma$ distribution is modelled with a Voigtian pdf, while the $m_{\mu^+\mu^-}$ distribution is modelled with a first order polynomial. The parameters of the former pdf are derived from the simulated $Z \rightarrow Q\gamma$ signal samples. The parameters of the latter pdf are determined directly in the fit to data.

To validate this background model with data, the $m_{Q\gamma}$ distributions in several regions defined by kinematic and isolation requirements looser than the nominal signal requirements are used to compare the prediction of the background model with the data. Three validation regions are defined using the GR selection as the basis and adding the p_T^Q requirement (VR1), the muon isolation requirements (VR2), or the photon isolation requirement (VR3). The $m_{Q\gamma}$ distributions in these validation regions are shown in Figure 3 for the $\psi(nS)\gamma$ and the $\Upsilon(nS)\gamma$ final states. The background model is found to describe the data well in all validation regions.

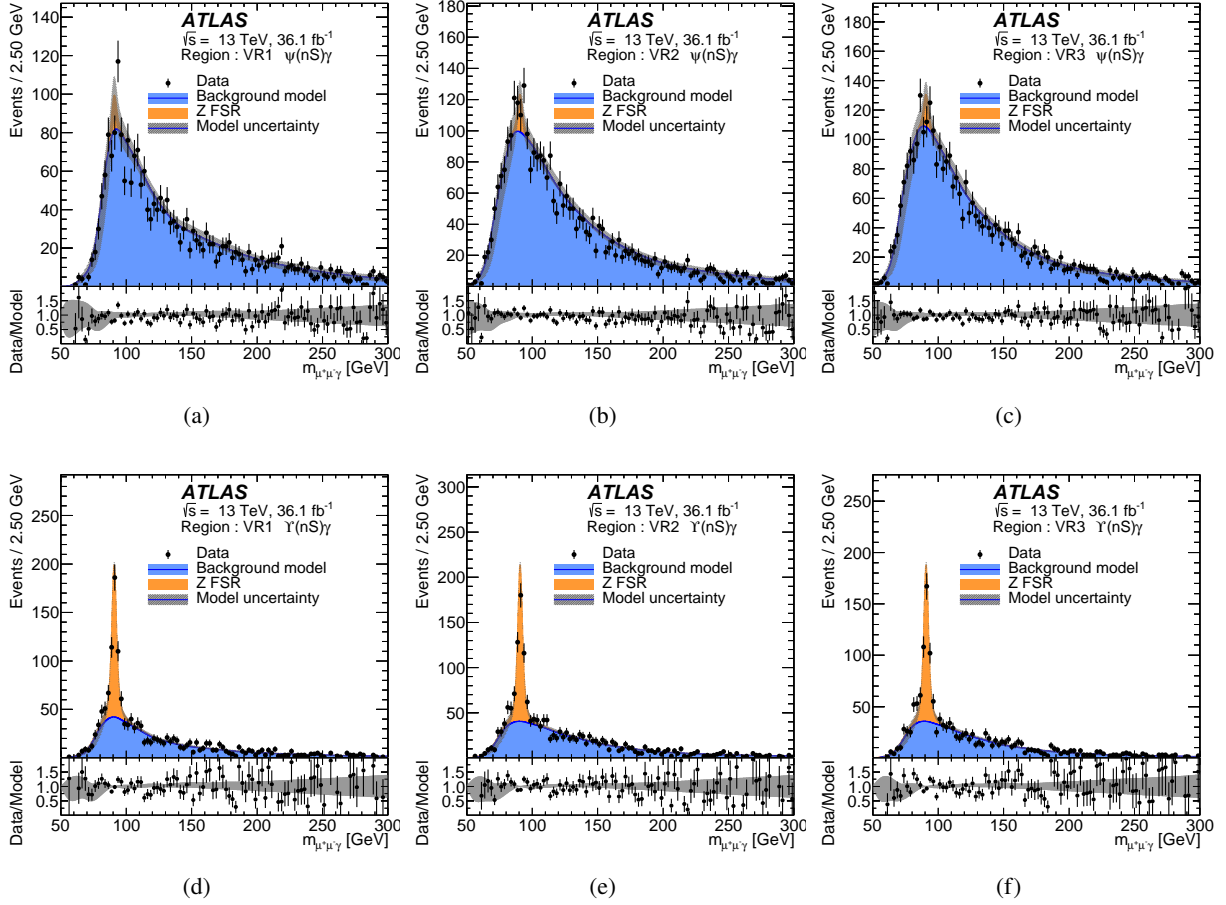

Figure 3: The distribution of $m_{\mu^+\mu^-\gamma}$ in data compared to the prediction of the background model for ((a), (b) and (c)) $H(Z) \rightarrow \psi(nS)\gamma$ and ((d), (e) and (f)) $H(Z) \rightarrow \Upsilon(nS)\gamma$ in the VR1, VR2 and VR3 validation regions. Z FSR refers to the $Z \rightarrow \mu^+\mu^-\gamma$ background contribution. The background model is normalised to the observed number of events within the region shown. The uncertainty band corresponds to the uncertainty envelope derived from variations in the background modelling procedure.

7 Systematic uncertainties

The systematic uncertainties in the expected signal yields are summarised in Table 1. Uncertainties in the Higgs production cross sections are obtained from Ref. [27]. The Z boson production cross section uncertainty is taken from the measurement in Ref. [60].

The uncertainty in the acceptance of the Higgs boson signal due to missing higher orders in the generator, parton distribution functions, underlying-event set of tuned parameters, and parton showering is estimated by studying the effect of the different variations on the acceptance at generator level. The total uncertainty in the acceptance due to these effects is estimated to be 1.8%. For the Z boson, the respective uncertainty is determined to be 6% by comparing the generator-level acceptance predictions of the nominal simulated sample with those of MADGRAPH5_AMC@NLO v2.2.2 [68] and SHERPA 2.2.1 [69].

Trigger efficiencies for photons are determined from samples enriched with $Z \rightarrow e^+e^-$ events in data [70]. The systematic uncertainty in the expected signal yield associated with the trigger efficiency is estimated

to be 2.0%. Photon identification efficiencies are determined using the enriched $Z \rightarrow e^+e^-$ events, as well as inclusive photon events and $Z \rightarrow \ell\ell\gamma$ events [66, 71]. The impact on the yields of the photon identification efficiency uncertainties, for both the converted and unconverted photons, are 1.4% for the Higgs and Z boson signals. The effect of the muon reconstruction and identification efficiency uncertainty is 2.8% [65].

The photon energy scale uncertainty, determined from $Z \rightarrow e^+e^-$ events and validated using $Z \rightarrow \ell\ell\gamma$ events [72, 73], is propagated through the simulated signal samples as a function of η^γ and p_T^γ . The uncertainty associated with the determination of the photon energy scale and resolution in the simulation is 0.3% in the yield of the Higgs and Z boson signal. Similarly, the systematic uncertainty associated with the scale of the muon momentum measurement is 0.2% [65]. The effect of the energy/momentum scale and resolution uncertainties on the signal shape is negligible for the Higgs and Z boson signals. For the Z FSR background shape, the effect is 0.2% on the value of the mean. Including the corresponding nuisance parameter results in a 0.5% change in the expected limit of the $Z \rightarrow \Upsilon(nS)\gamma$ channels with negligible impact in the other channels.

The shape of the background model is allowed to vary around the nominal shape, and the parameters controlling these systematic variations are treated as nuisance parameters in the maximum-likelihood fit described in Section 8. Three such shape variations are implemented through scale variations on the p_T^γ distribution in the model, linear distortions of the shape of the $\Delta\phi(Q, \gamma)$ distribution, and a global tilt of the three-body mass distribution around a pivot point. The first two variations are straightforward alterations to the underlying kinematics of the pseudocandidates, which cause corresponding changes in the three-body mass. The third variation is applied directly to the final three-body mass template. These systematic uncertainties allow the background template to adjust to the observed data.

Table 1: Summary of the systematic uncertainties in the expected signal yields.

Source of systematic uncertainty	Yield uncertainty
	$H(Z) \rightarrow Q\gamma$
Total $H(Z)$ cross section	7.0% (2.9%)
Integrated luminosity	2.1%
$H(Z)$ QCD modelling	1.8% (6%)
Trigger efficiency	2.0%
Photon identification	1.4%
Muon reconstruction	2.8%
Photon energy scale	0.3%
Muon momentum scale	0.2%

8 Results

The data are compared with background and signal predictions using a two-dimensional (2D) simultaneous unbinned maximum-likelihood fit to the $m_{\mu^+\mu^-\gamma}$ and $m_{\mu^+\mu^-}$ distributions. A simultaneous 2D fit is required to distinguish the Z FSR background from the $Z \rightarrow Q\gamma$ signal and the non-resonant background. The parameters of interest are the Higgs and Z boson signal normalisations. Systematic uncertainties are modelled using additional nuisance parameters in the fit; in particular, the background normalisations are free parameters. The fit uses the selected events with $m_{Q\gamma} < 300$ GeV.

In total, 1033 events were observed in the $\psi(nS)\gamma$ and 906 in the $\Upsilon(nS)\gamma$ signal regions. The expected and observed numbers of background events within the $m_{Q\gamma}$ ranges relevant to the Higgs and Z boson signals are shown in Table 2. The results of the background-only fits for the $\psi(nS)\gamma$ and $\Upsilon(nS)\gamma$ analyses are shown in Figure 4.

Table 2: The number of observed events and the mean expected background, with its total uncertainty, for the $m_{Q\gamma}$ ranges of interest. The expected Z and Higgs boson contributions are shown for branching fraction values of 10^{-6} and 10^{-3} , respectively.

$m_{\mu^+\mu^-}$ mass range [GeV]		Observed (expected) background		Z signal for $\mathcal{B} = 10^{-6}$	H signal for $\mathcal{B} = 10^{-3}$
		$m_{\mu^+\mu^-\gamma}$ mass range [GeV]			
		81–101	120–130		
$J/\psi\,\gamma$	2.9–3.3	92 (89 \pm 6)	20 (23.6 \pm 1.3)	13.7 \pm 1.1	22.2 \pm 1.9
$\psi(2S)\,\gamma$	3.5–3.9	43 (42 \pm 5)	8 (10.0 \pm 0.8)	1.82 \pm 0.14	2.96 \pm 0.25
$\Upsilon(1S)\,\gamma$	9.0–10.0	115 (126 \pm 8)	9 (13.6 \pm 1.2)	7.8 \pm 0.6	10.7 \pm 0.9
$\Upsilon(2S)\,\gamma$	9.5–10.5	106 (121 \pm 8)	8 (12.6 \pm 1.4)	5.9 \pm 0.5	8.1 \pm 0.7
$\Upsilon(3S)\,\gamma$	10.0–11.0	112 (113 \pm 8)	7 (10.6 \pm 1.2)	7.1 \pm 0.6	9.2 \pm 0.8

The systematic uncertainties described in Section 7 result in a 1.0% increase of the expected 95% CL upper limit on the branching fraction of the $H \rightarrow \psi(nS)\gamma$ decays. For the $Z \rightarrow \psi(nS)\gamma$ decays, the effect is larger, 2.6%, mostly due to the systematic uncertainty in the background shape. Similar behaviour is observed in the $\Upsilon(nS)\gamma$ analysis with systematic uncertainties resulting in a 2.5–2.7% deterioration in the sensitivity to the $H \rightarrow \Upsilon(nS)\gamma$ decays and a 2.8–2.9% deterioration in the sensitivity to the $Z \rightarrow \Upsilon(nS)\gamma$ decays, also mostly due to the systematic uncertainty in the background shape.

On the basis of the fit to the observed data, the largest excess observed is 2.2σ in the search for $Z \rightarrow J/\psi\gamma$. Upper limits are set on the branching fractions for the Higgs and Z boson decays into $Q\gamma$ using the CL_s modified frequentist formalism [74] with the profile-likelihood-ratio test statistic [75] and the asymptotic approximations derived in Ref. [76]. The expected SM production cross section is assumed for the Higgs boson [27], while the ATLAS measurement of the inclusive Z boson cross section is used for the Z boson signal [60], as discussed in Section 3. The results are summarised in Table 3. The observed 95% CL upper limits on the branching fractions for Higgs and Z boson decays into $J/\psi\gamma$ and $\psi(2S)\gamma$ are $(3.5, 20) \times 10^{-4}$ and $(2.3, 4.5) \times 10^{-6}$, respectively. The corresponding limits for the Higgs and Z boson decays into $\Upsilon(nS)\gamma$ ($n = 1, 2, 3$) are $(4.9, 5.9, 5.7) \times 10^{-4}$ and $(2.8, 1.7, 4.8) \times 10^{-6}$, respectively. Upper limits at 95% CL on the product of the production cross section times branching fraction are determined for the Higgs boson decays, yielding 19 fb for the $H \rightarrow J/\psi\gamma$ decay, 110 fb for the $H \rightarrow \psi(2S)\gamma$ decay, and (28, 33, 32) fb for the $H \rightarrow \Upsilon(nS)\gamma$ ($n = 1, 2, 3$) decays.

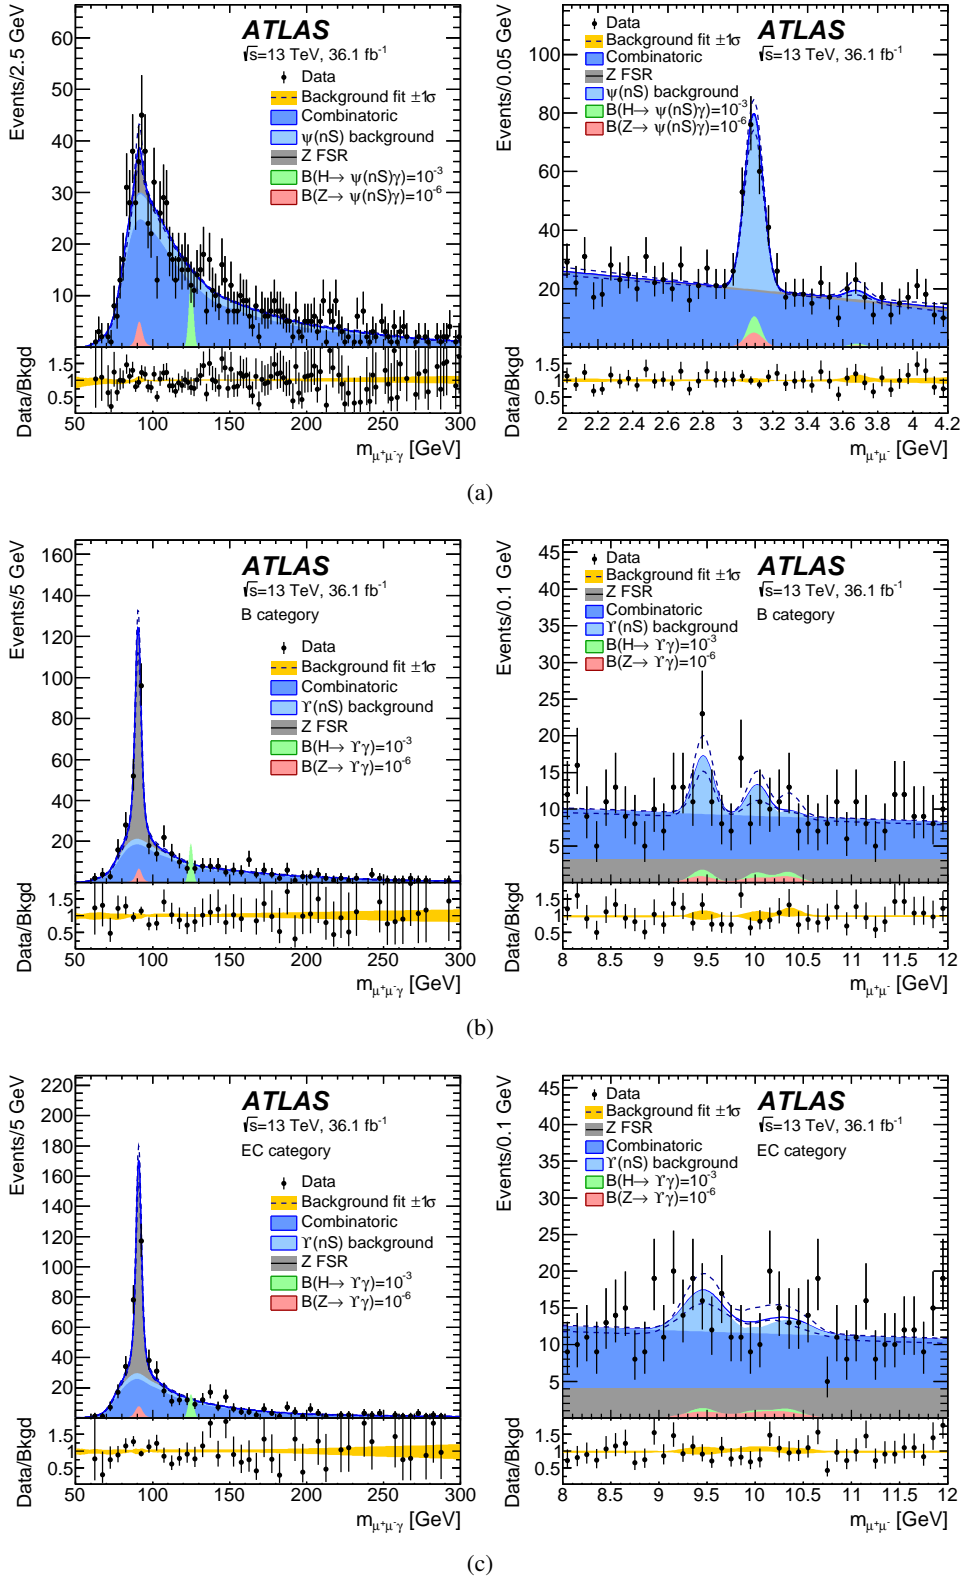

Figure 4: The $m_{\mu^+\mu^-\gamma}$ and $m_{\mu^+\mu^-}$ distributions for the selected (a) $\psi(nS)\gamma$ and $\Upsilon(nS)\gamma$ ((b) barrel and (c) endcap categories) candidates along with the results of the maximum-likelihood fits with background-only models. Z FSR refers to the $Z \rightarrow \mu^+\mu^-\gamma$ background contribution. The ratios of the data to the background-only fits are also shown.

Table 3: Expected and observed branching fraction upper limits at 95% CL for the $H(Z) \rightarrow J/\psi \gamma$, $H(Z) \rightarrow \psi(2S) \gamma$, and $H(Z) \rightarrow \Upsilon(nS) \gamma$ ($n = 1, 2, 3$) analyses, assuming SM production for the Higgs and Z bosons. The $\pm 1\sigma$ intervals of the expected limits are also given.

Branching fraction limit (95% CL)	Expected	Observed
$\mathcal{B}(H \rightarrow J/\psi \gamma) [10^{-4}]$	$3.0^{+1.4}_{-0.8}$	3.5
$\mathcal{B}(H \rightarrow \psi(2S) \gamma) [10^{-4}]$	$15.6^{+7.7}_{-4.4}$	19.8
$\mathcal{B}(Z \rightarrow J/\psi \gamma) [10^{-6}]$	$1.1^{+0.5}_{-0.3}$	2.3
$\mathcal{B}(Z \rightarrow \psi(2S) \gamma) [10^{-6}]$	$6.0^{+2.7}_{-1.7}$	4.5
$\mathcal{B}(H \rightarrow \Upsilon(1S) \gamma) [10^{-4}]$	$5.0^{+2.4}_{-1.4}$	4.9
$\mathcal{B}(H \rightarrow \Upsilon(2S) \gamma) [10^{-4}]$	$6.2^{+3.0}_{-1.7}$	5.9
$\mathcal{B}(H \rightarrow \Upsilon(3S) \gamma) [10^{-4}]$	$5.0^{+2.5}_{-1.4}$	5.7
$\mathcal{B}(Z \rightarrow \Upsilon(1S) \gamma) [10^{-6}]$	$2.8^{+1.2}_{-0.8}$	2.8
$\mathcal{B}(Z \rightarrow \Upsilon(2S) \gamma) [10^{-6}]$	$3.8^{+1.6}_{-1.1}$	1.7
$\mathcal{B}(Z \rightarrow \Upsilon(3S) \gamma) [10^{-6}]$	$3.0^{+1.3}_{-0.8}$	4.8

9 Summary

Searches for the exclusive decays of Higgs and Z bosons into $J/\psi \gamma$, $\psi(2S) \gamma$, and $\Upsilon(nS) \gamma$ have been performed with a $\sqrt{s} = 13$ TeV pp collision data sample collected with the ATLAS detector at the LHC corresponding to an integrated luminosity of 36.1 fb^{-1} . No significant excess of events is observed above the background expectations. The obtained 95% CL upper limits are $\mathcal{B}(H \rightarrow J/\psi \gamma) < 3.5 \times 10^{-4}$ and $\mathcal{B}(Z \rightarrow J/\psi \gamma) < 2.3 \times 10^{-6}$ for the $J/\psi \gamma$ final state. The corresponding upper limits are $\mathcal{B}(H \rightarrow \psi(2S) \gamma) < 2.0 \times 10^{-3}$ and $\mathcal{B}(Z \rightarrow \psi(2S) \gamma) < 4.5 \times 10^{-6}$ for the $\psi(2S) \gamma$ final state. The 95% CL upper limits $\mathcal{B}(H \rightarrow \Upsilon(nS) \gamma) < (4.9, 5.9, 5.7) \times 10^{-4}$ and $\mathcal{B}(Z \rightarrow \Upsilon(nS) \gamma) < (2.8, 1.7, 4.8) \times 10^{-6}$ are set for the $\Upsilon(nS) \gamma$ ($n = 1, 2, 3$) final states. These upper limits represent an improvement by a factor of approximately two relative to the earlier $H(Z) \rightarrow J/\psi \gamma$ and $H(Z) \rightarrow \Upsilon(nS) \gamma$ results from the ATLAS Collaboration using up to 20.3 fb^{-1} of $\sqrt{s} = 8$ TeV pp collision data with the addition of the first upper limits on the $H/Z \rightarrow \psi(2S) \gamma$ decays.

Acknowledgements

We thank CERN for the very successful operation of the LHC, as well as the support staff from our institutions without whom ATLAS could not be operated efficiently.

We acknowledge the support of ANPCyT, Argentina; YerPhI, Armenia; ARC, Australia; BMWFW and FWF, Austria; ANAS, Azerbaijan; SSTC, Belarus; CNPq and FAPESP, Brazil; NSERC, NRC and CFI, Canada; CERN; CONICYT, Chile; CAS, MOST and NSFC, China; COLCIENCIAS, Colombia; MSMT CR, MPO CR and VSC CR, Czech Republic; DNRF and DNSRC, Denmark; IN2P3-CNRS, CEA-DRF/IRFU, France; SRNSFG, Georgia; BMBF, HGF, and MPG, Germany; GSRT, Greece; RGC, Hong Kong SAR, China; ISF, I-CORE and Benoziyo Center, Israel; INFN, Italy; MEXT and JSPS, Japan; CNRST, Morocco; NWO, Netherlands; RCN, Norway; MNiSW and NCN, Poland; FCT, Portugal;

- ^b Also at Centre for High Performance Computing, CSIR Campus, Rosebank, Cape Town; South Africa.
- ^c Also at CERN, Geneva; Switzerland.
- ^d Also at CPPM, Aix-Marseille Université, CNRS/IN2P3, Marseille; France.
- ^e Also at Département de Physique Nucléaire et Corpusculaire, Université de Genève, Genève; Switzerland.
- ^f Also at Departament de Física de la Universitat Autònoma de Barcelona, Barcelona; Spain.
- ^g Also at Departamento de Física Teórica y del Cosmos, Universidad de Granada, Granada (Spain); Spain.
- ^h Also at Department of Applied Physics and Astronomy, University of Sharjah, Sharjah; United Arab Emirates.
- ⁱ Also at Department of Financial and Management Engineering, University of the Aegean, Chios; Greece.
- ^j Also at Department of Physics and Astronomy, University of Louisville, Louisville, KY; United States of America.
- ^k Also at Department of Physics and Astronomy, University of Sheffield, Sheffield; United Kingdom.
- ^l Also at Department of Physics, California State University, Fresno CA; United States of America.
- ^m Also at Department of Physics, California State University, Sacramento CA; United States of America.
- ⁿ Also at Department of Physics, King's College London, London; United Kingdom.
- ^o Also at Department of Physics, St. Petersburg State Polytechnical University, St. Petersburg; Russia.
- ^p Also at Department of Physics, University of Fribourg, Fribourg; Switzerland.
- ^q Also at Department of Physics, University of Michigan, Ann Arbor MI; United States of America.
- ^r Also at Dipartimento di Fisica E. Fermi, Università di Pisa, Pisa; Italy.
- ^s Also at Giresun University, Faculty of Engineering, Giresun; Turkey.
- ^t Also at Graduate School of Science, Osaka University, Osaka; Japan.
- ^u Also at Hellenic Open University, Patras; Greece.
- ^v Also at Horia Hulubei National Institute of Physics and Nuclear Engineering, Bucharest; Romania.
- ^w Also at II. Physikalisches Institut, Georg-August-Universität Göttingen, Göttingen; Germany.
- ^x Also at Institutio Catalana de Recerca i Estudis Avancats, ICREA, Barcelona; Spain.
- ^y Also at Institute for Mathematics, Astrophysics and Particle Physics, Radboud University

Nijmegen/Nikhef, Nijmegen; Netherlands.

^z Also at Institute for Particle and Nuclear Physics, Wigner Research Centre for Physics, Budapest; Hungary.

^{aa} Also at Institute of Particle Physics (IPP); Canada.

^{ab} Also at Institute of Physics, Academia Sinica, Taipei; Taiwan.

^{ac} Also at Institute of Physics, Azerbaijan Academy of Sciences, Baku; Azerbaijan.

^{ad} Also at Institute of Theoretical Physics, Ilia State University, Tbilisi; Georgia.

^{ae} Also at LAL, Université Paris-Sud, CNRS/IN2P3, Université Paris-Saclay, Orsay; France.

^{af} Also at Louisiana Tech University, Ruston LA; United States of America.

^{ag} Also at Manhattan College, New York NY; United States of America.

^{ah} Also at Moscow Institute of Physics and Technology State University, Dolgoprudny; Russia.

^{ai} Also at National Research Nuclear University MEPhI, Moscow; Russia.

^{aj} Also at Near East University, Nicosia, North Cyprus, Mersin; Turkey.

^{ak} Also at Physikalisches Institut, Albert-Ludwigs-Universität Freiburg, Freiburg; Germany.

^{al} Also at School of Physics, Sun Yat-sen University, Guangzhou; China.

^{am} Also at The City College of New York, New York NY; United States of America.

^{an} Also at The Collaborative Innovation Center of Quantum Matter (CICQM), Beijing; China.

^{ao} Also at Tomsk State University, Tomsk, and Moscow Institute of Physics and Technology State University, Dolgoprudny; Russia.

^{ap} Also at TRIUMF, Vancouver BC; Canada.

^{aq} Also at Università di Napoli Parthenope, Napoli; Italy.
